

You are invited to participate in a webinar entitled:

Grapevine Red Blotch Disease:

What You Need to Know

Friday, February 26, 2016

10:00am Pacific time

Summary:

Grapevine red blotch disease and the virus associated with it has been confirmed in many major grape production regions of the United States and Canada. Since the identification of the virus in 2011, several teams of researchers from across North America have been intensely characterizing the disease and effects on grapevines, as well as characterizing the virus, its spread, and potential management. Considerable progress has been made, but much remains unknown. Speakers representing many of these labs will be presenting their work and what it means for the grape industry.

REGISTER

Webinar Agenda

Friday, February 26, 2016 (note: all times are *Pacific*)

- 10:00 **Welcome and Introduction**
Frank Zalom, UC Davis
- 10:05 **History of red blotch, symptoms and significance**
Mysore Sudarshana, USDA-ARS, Davis, CA
- 10:20 **Etiology of red blotch**
Marc Fuchs, Cornell University, Geneva, NY
- 10:35 **Detection and genetic diversity of the virus**
Keith Perry, Cornell University, Ithaca, NY
- 10:50 **Effect of red blotch on grapevine performance**
Rhonda Smith, UC Cooperative Extension
- 11:05 **Red blotch situation in Oregon**
Vaughn Walton, Oregon State University and
Bob Martin, USDA-ARS, Corvallis, OR
- 11:20 **Red blotch and the virus in Canada**
Sudarsana Poojari, Agri-Canada, Canada, T. Lowery, A-M. Schmidt, M. Rott,
W. Mcfadden-Smith and J.R. Urbez-Torre
- 11:35 **Red blotch and the virus in Europe**
Jean-Sebastian Reynard, Agroscope, Switzerland
- 11:50 **Virus Spread, disease gradient, and insects**
Brian Bahder, UC Davis
- 12:05 **FPS and NCPN, Protecting the supply chain of grapevines from red blotch**
Deborah Golino, FPS, UC Davis
- 12:20 **Question and Answer**
Speakers (moderated by Frank)

Regional Pest Alert

Grapevine Red Blotch-associated Virus

Red leaf symptoms that differed from other known red leaf diseases affecting grape foliage were first noticed in vineyards planted with red wine grape cultivars in Napa County, California, in 2008. A virus now known as Grapevine red blotch-associated virus (GRBaV) was subsequently identified in grapevines exhibiting red blotch symptoms in 2011. It is now confirmed that red blotch disease is present in many major grape production regions of the United States and Canada.

Red Blotch Disease Symptoms

Leaf symptoms first appear approximately mid-summer; however, timing of symptom expression differs among grapevine cultivars and year. In red-fruited cultivars, common symptoms include red blotches originating from the leaf margin or within the leaf blade and primary and secondary veins that often turn red. In white fruit cultivars, symptoms appear as pale green to pale yellow patches. Symptoms usually start on basal leaves and progress up the shoot. In some cultivars, such as 'Chardonnay' and 'Zinfandel', marginal burning may occur similar to severe potassium deficiency. In some red-fruited cultivars such as 'Malbec' and 'Mourvèdre', the entire blade may turn red by harvest. Foliar symptoms are generally distinct from those of grapevine leafroll disease (GLD) early in the season, but leaf blade coloration may resemble those of GLD by late fall. At this time, red blotch disease is not known to kill grapevines.

Effect of Red Blotch Disease on Fruit

The effect of the virus infection on yield and fruit quality parameters appears to vary among cultivars. However, total soluble solids are consistently reduced in juice produced from fruit on diseased grapevines. The effect on pH and titratable acidity is also variable.

The Virus

GRBaV is a virus similar in genome organization to geminiviruses and is comprised of a single circular DNA molecule with ~3206 nucleotides. The virus can be detected using a laboratory PCR test. The virus appears to have become widely spread through infected

material used for propagation. Commercial testing is available from several plant virus testing laboratories in the USA.

The clustered and/or leading edge patterns of disease incidence in vineyards resemble that of movement by insects not commonly found feeding on grapevines; however, no vector has been identified to date.

Guidelines for Management

Plant vines produced from GRBaV-tested scion and rootstock source material. In established vineyards, suspect grapevines showing red blotch symptoms should be flagged and tested by a commercial lab to confirm the presence of GRBaV. If positive, a decision on whether to rogue and replant infected vines needs to be made. The epidemiology of GRBaV is not currently known, therefore the decision to rogue will likely be based on the economic impacts of GRBaV on fruit quality. There is no “cure” for a virus infected vine at this time, and there are no chemicals known to control for GRBaV. Because a vector remains unconfirmed, there are no pesticide recommendations that would target a vector at this time.

About the UC Cooperative Extension

The University of California Cooperative Extension offices are local problem-solving centers. Campus-based specialists and county-based farm, home and youth advisors work as teams to bring the University's research-based information to Californians. UCCE is a full partnership of federal, state, county, and private resources linked in applied research and educational outreach. UCCE develops and extends timely and pertinent information in a manner, which is independent, unbiased, noncommercial, and research based. These fundamental criteria set it apart from all other information resources.
